

CRITICAL THINKING TASK

Basic Syntax for a for loop.

```
for (initialization statement; condition expression; update expression) {
    body
}
```

Basic Syntax for a while loop.

```
while (condition expression) {
    body
}
```

A while loop is a more versatile loop where the initialization and update statement can be written anywhere throughout the code in the body. It is interesting that every for loop can be a while loop but the other way around is just not possible.

To Change a for loop to a while loop:

<pre>for (<i>initialization statement</i>; <i>condition</i> <i>expression</i>; <i>update expression</i>) { <i>body</i> }</pre>	<pre>--initialization statement-- while (<i>condition expression</i>) { <i>body</i> --update expression-- }</pre>
--	---

Text Description:

To convert a for loop to a while loop, follow these steps:

1. Take the initialization statement of the for loop and place it before the while loop.
2. Take the condition expression of the for loop and place it inside the parentheses after the while keyword.
3. Take the update expression of the for loop and place it as a separate statement after the body of the while loop.
4. Place the body of the for loop inside the curly braces of the while loop.
